

LINEAR PROGRAMMING EXAMPLE:

BAKERY:

INGREDIENTS NEEDED TO MAKE

	Flour	Sugar	Eggs
Donuts	$2x$	$2x$	$7x$
Cake	$5y$	$9y$	$12y$
INGREDIENTS AVAILABLE: ≤ 200 ≤ 300 ≤ 500			

PROFIT PER DONUTS = 5 PER CAKE = 25

How many cakes / donuts to make
to maximise profit?

Decision Variables:

$x \rightarrow$ # of donuts

$y \rightarrow$ # of cakes

linear
constraints \rightarrow

200 units of
Flour \Rightarrow

$$2x + 5y \leq 200$$

Sugar \Rightarrow

$$2x + 9y \leq 300$$

$$7x + 12y \leq 500$$

Maximise

$$5x + 25y$$

\nwarrow LINEAR
OBJECTIVE.

LINEAR PROGRAMMING EXAMPLE 2

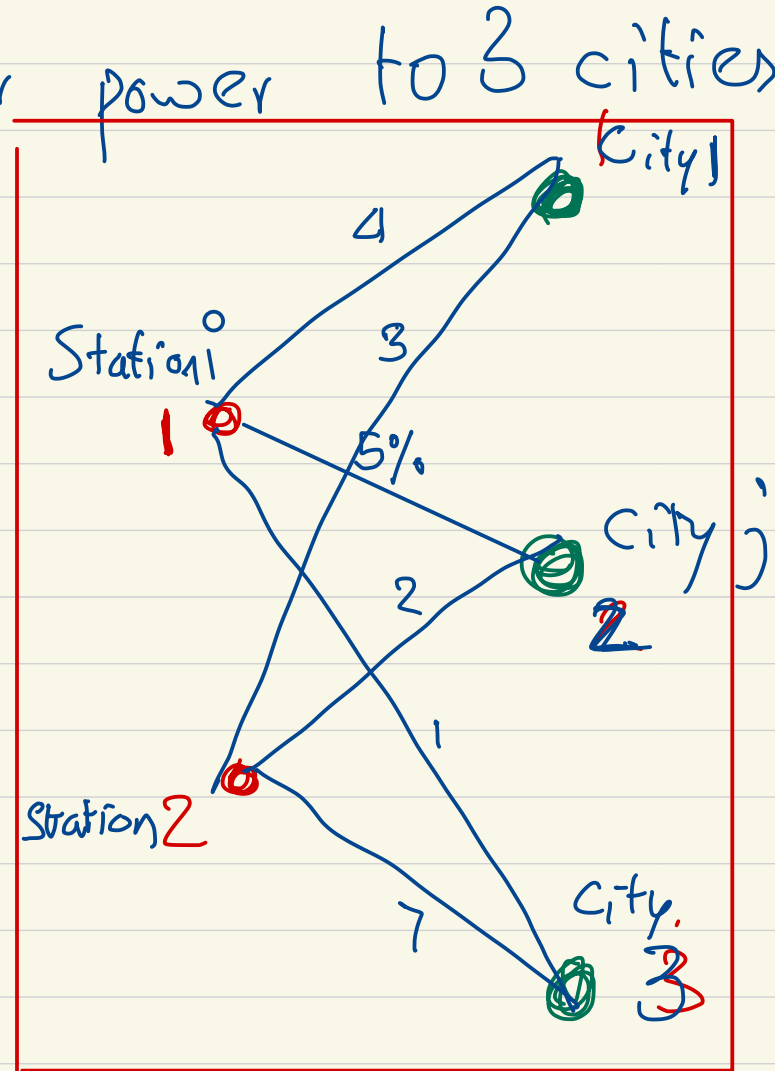

POWER STATIONS

* 2 power stations that deliver power to 3 cities

* DEMAND:

City	Demand
1	40
2	60
3	80

* Each unit of power from Station i to City j incurs loss = weight of edge ij

Minimise loss while meeting the demand.

Variables:

P_{ij} = power sent from station i
to city j .

$$P_{ij} \geq 0$$

Constraints:

City 1 Demand 40 :

$$P_{11} + P_{21} \geq 40$$

City 2 " 60 :

$$P_{12} + P_{22} \geq 60$$

City " 80 :

$$P_{13} + P_{23} \geq 80$$

Minimize : $4P_{11} + 5P_{12} + P_{13} + 3P_{21} + 2P_{22} + 7P_{23}$

A
B
C
D
E

$$\begin{aligned} &\text{Max } \underline{x + 2y} \quad \checkmark \\ &\text{subject to } x \leq 3 \\ &\quad (x + y \leq 5) \\ &\quad (y - 3x \leq 1) \\ &\quad x, y \geq 0 \end{aligned} \quad \left. \vphantom{\begin{aligned} &\text{subject to } x \leq 3 \\ &\quad (x + y \leq 5) \\ &\quad (y - 3x \leq 1) \\ &\quad x, y \geq 0 \end{aligned}} \right\} \text{Cost}$$

TERMINOLOGY

Polytope = Feasible region of a linear program.

Vertex/Corner = A point x in the feasible region that lies at intersection of " n " hyperplanes (a.k.a. n faces) specified by constraints.

- Example:
- 1) In 2-dimensions, a vertex is intersection of 2 lines
 - 2) In 3-dimensions, a vertex is intersection of 3 faces.

FEASIBLE REGION: Set of points satisfying all constraints.

FACT 1: Feasible region of a linear program is always CONVEX

FACT 2: If linear program, there is a optimal solution, which is a "vertex" corner

CONVEX SET

A set of points $S \subseteq \mathbb{R}^d$ is convex

if $\forall x, y \in S$

\Rightarrow line segment joining $x, y \in S$

CONVEX

CONVEX

NOT CONVEX

OPTIMAL SOLUTION:

$$\text{Max } x+2y \quad \checkmark$$

$$\text{subj. to. } x \leq 3$$

$$A \rightarrow (x+y \leq 5)$$

$$B \rightarrow (-3x+y \leq 1)$$

$$x \geq 0$$

$$y \geq 0$$

SIMPLEX ALG:

* Start at some vertex

$$\text{Ex: } (0,0)$$

* Keep moving to neighboring vertex to increase objective

$$(0,0) \rightarrow (3,0) \rightarrow (3,2) \rightarrow (1,4)$$

REMARK: 1) Simplex can take exponential time in general, but is very efficient and widely used in practice

2) Linear programs can be solved in polynomial time!

by using

a) 'Ellipsoid Algorithm'

b) "Interior point methods"

Linear Program

Variables: $\underbrace{x_1, \dots, x_n}_{n \text{ variables}} \in \mathbb{R}^n$

Constraints:

Input: $\{a_{ij}, b_j\}$

m constraints

$$a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n \leq b_1$$

$$a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n \leq b_2$$

\vdots

$$a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n \leq b_m$$

Maximise $C_1x_1 + C_2x_2 + \dots + C_nx_n$

LISTING ALL "VERTICES" OF A FEASIBLE REGION OF LP

Given an LP $\{ \sum a_{ij} x_j \leq b_j : j=1 \dots m \}$

For each subset of n constraints:

→ Solve for point of intersection x^*
(solving linear system / Gaussian elimination)

→ If x^* is feasible (satisfies all remaining constraints)
then x^* is a vertex.

THEREFORE

{ # of vertices of
an LP with
 n variables & m constraints }

can be as
large as
 $\binom{m}{n} \approx \text{exponential in } n.$

SIMPLEX ALG:

* Start at vertex v

* Find a neighboring vertex of higher objective value and move there, REPEAT.

Number of neighboring vertices

Example: Suppose an LP has 6 constraints with
 $\{A, B, C, D, E, F\}$
and 3 variables

Consider a vertex \coloneqq intersection of A, B, C

its neighbors are intersections of

{	A, B, D	A, D, C	D, A, C	}
	A, B, E	A, E, C	E, A, C	
	A, B, F	A, F, C	F, A, C	

i.e. Remove one constraint from $\{A, B, C\}$ add one from $\{D, E, F\}$.

In general,

for a vertex v of an LP with n variables
and m constraints

$$\# \text{neighbors} \leq (m-n) \cdot n$$
