EECS 16A
fun stuff: computational imaging

EECS16A: course evaluations

- course-evaluations.berkeley.edu

Overdetermined system: use least squares

$$\begin{matrix} A \\ \times \\ b \end{matrix} = \begin{matrix} x \end{matrix}$$

- the least-squares solution “minimally perturbs” b

$$\hat{x} = (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{A}^T \vec{b}$$

Underdetermined system: ???

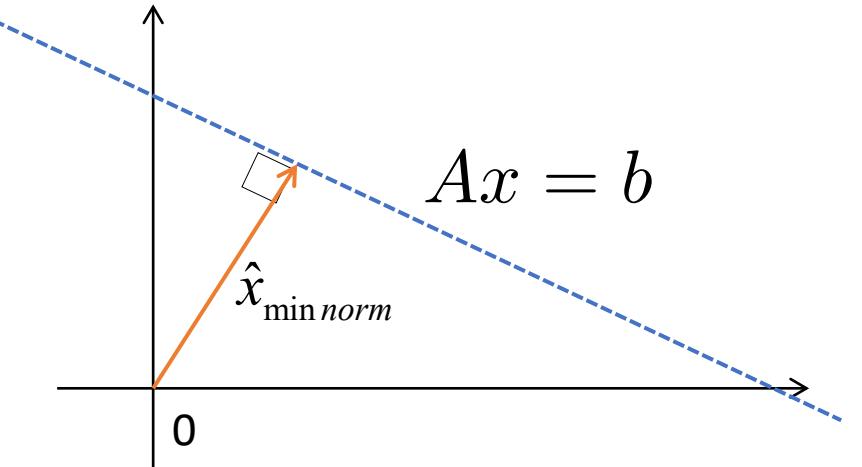

$$A \quad x = b$$

IF TV SCIENCE WAS MORE LIKE REAL SCIENCE

Underdetermined system: ???

$$A \quad x = b$$

- Can be infinite valid solutions!
- Ideas: pick the ‘smallest’ one? The ‘sparsest’?
 - e.g. min norm:

$$\hat{x}_{\min norm} = \mathbf{A}^T (\mathbf{A} \mathbf{A}^T)^{-1} \vec{b}$$

So far, we've only talked about 'overdetermined systems':

$$\begin{array}{c} \text{m} \\ \text{m}\times n \\ \leftarrow n \rightarrow \end{array} \quad \begin{array}{c} \text{n} \\ \text{n}\times 1 \\ \uparrow \downarrow \end{array} = \begin{array}{c} \text{m} \\ \text{m}\times 1 \end{array}$$

m > n "overdetermined"

$$A\vec{x} = \vec{b}$$

Recall: for least squares sol'n we minimized error:

$$\min \|\vec{e}\|^2 = \min_{\vec{x}} \|A\vec{x} - \vec{b}\|^2$$

$$\hookrightarrow \hat{\vec{x}} = (A^T A)^{-1} A^T \vec{b}$$

What if problem is "underdetermined"? Infinite sol'n (more unknowns than eqns)

↳ (though 0 sol'n if inconsistent)

$$\begin{array}{c} \text{m} \\ \text{m}\times n \\ \leftarrow n \rightarrow \end{array} \quad \begin{array}{c} \text{m} \\ \text{m}\times 1 \\ \uparrow \downarrow \end{array} = \begin{array}{c} \text{m} \\ \text{m}\times 1 \end{array}$$

m < n

But, can we find a good estimate?

↳ Yes, in special cases!

e.g. sparsity (most entries are zero)

Example: We could look for 'smallest' \rightarrow min norm solution: $\begin{bmatrix} 1 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 1 \end{bmatrix} \rightarrow x_1 + x_2 = 1$
smallest sol'n:
 $x_1 = 0.5, x_2 = 0.5$

$\min_{\vec{x}} \|\vec{x}\|^2$ such that $A\vec{x} = \vec{b}$ (constrained optimization) $\longrightarrow \hat{\vec{x}} = A^T (AA^T)^{-1} \vec{b}$

$$\min_{\vec{x}, \lambda} \|\vec{x}\|^2 + \vec{\lambda}^T (\vec{b} - A\vec{x})$$

to understand this, take
EE 127

$$\text{take } \frac{\partial}{\partial \vec{x}} (\vec{x}^T \vec{x} + \vec{\lambda}^T (\vec{b} - A\vec{x})) = 0$$

$$\begin{aligned} A 2\vec{x}^T - A\vec{\lambda}^T A &= \mathbf{0} \\ \vec{\lambda} &= (A^T A)^{-1} 2A\vec{x} \end{aligned}$$

$$\text{take deriv. } A\vec{x} = \vec{b}$$

$$\vec{\lambda} = (A^T A)^{-1} 2\vec{b}$$

$$\vec{x} = A^T (AA^T)^{-1} \vec{b}$$

Minimum norm sol'n!

'Sparsity' tells us how 'dense' the solution is

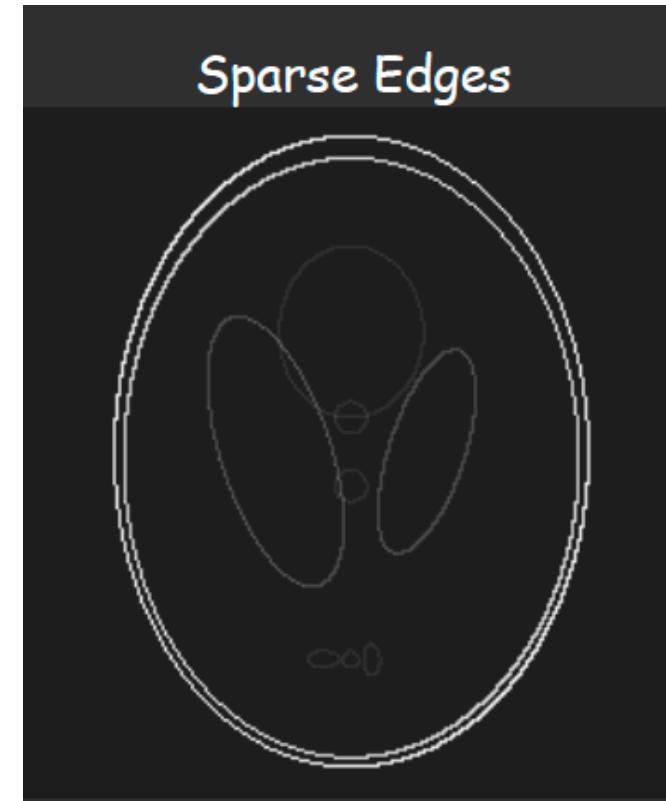

$$A \quad = \quad b$$
$$x$$

The fraction of non-zero elements in a matrix is called the ***sparsity*** (e.g. here k=5 for x vector)

Sometimes not-sparse things are sparse in a different basis

Take |derivatives|

How can we use sparsity for good?

Example: image compression

Reduce memory by smartly choosing which information to throw away

No compression

23:1 compression

144:1 compression

sparsity

Image compression:

ML: dictionary learning is all about finding a good basis transform to make sparse.

$$\begin{bmatrix} \text{not sparse} \\ x \\ \end{bmatrix}_{n \times 1} = \begin{bmatrix} \Psi & \end{bmatrix}_{n \times n} \begin{bmatrix} \text{sparse} \\ s \\ \end{bmatrix}_{n \times 1}$$

but mostly zeros!

transform matrix
change of basis
↳ DCT, FFT, etc.

Sparse x means only a few columns of A ‘matter’

$$\begin{matrix} \text{Image} \\ \downarrow \\ \text{Vector } x \\ \downarrow \\ \text{Vector } b \end{matrix} = \begin{matrix} \text{Matrix } A \\ \downarrow \\ \text{Vector } x \\ \downarrow \\ \text{Vector } b \end{matrix}$$

Sparse x means only a few columns of A ‘matter’

The diagram illustrates a matrix multiplication operation:

$$\begin{matrix} & \text{Matrix } A \\ \begin{matrix} \text{Sparse Vector } x \\ = \end{matrix} & \times \end{matrix}$$

Matrix A is a 5x10 grid of pixels. It has a uniform gray background with several small, scattered colored blocks (red, yellow, black) primarily concentrated in the rightmost two columns. This represents a sparse matrix where only a few columns have non-zero values.

The sparse vector x is represented by a vertical column of colored blocks. It consists of four distinct horizontal bands: a top band of orange, a middle band of yellow, a bottom band of light yellow, and a bottom-most band of black. The width of each band corresponds to the width of the colored blocks in the rightmost two columns of matrix A .

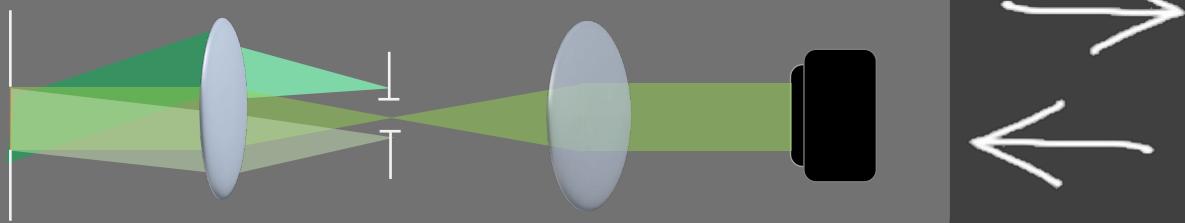

The resulting product is a vertical column of colored blocks, which is identical in structure to the sparse vector x . This visualizes how the sparse nature of x allows us to ignore most of the columns in A during the multiplication process.

If we knew which elements were non-zero, we could solve a small least squares problem:

$$\begin{matrix} \text{[Matrix A]} & \times & \text{[Vector b]} \\ = & & \text{[Vector y]} \end{matrix}$$

Computational Imaging

Hardware Design

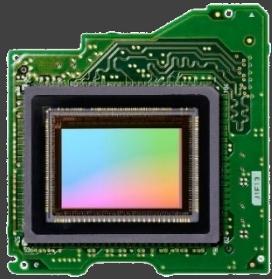

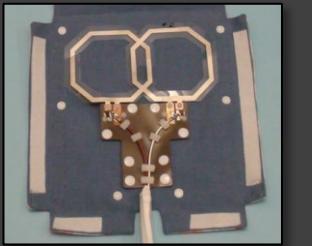

Computation Design

find x

$$\text{such that } y = |Ax|^2$$

The hard part is *integration*

Hardware Toolbox

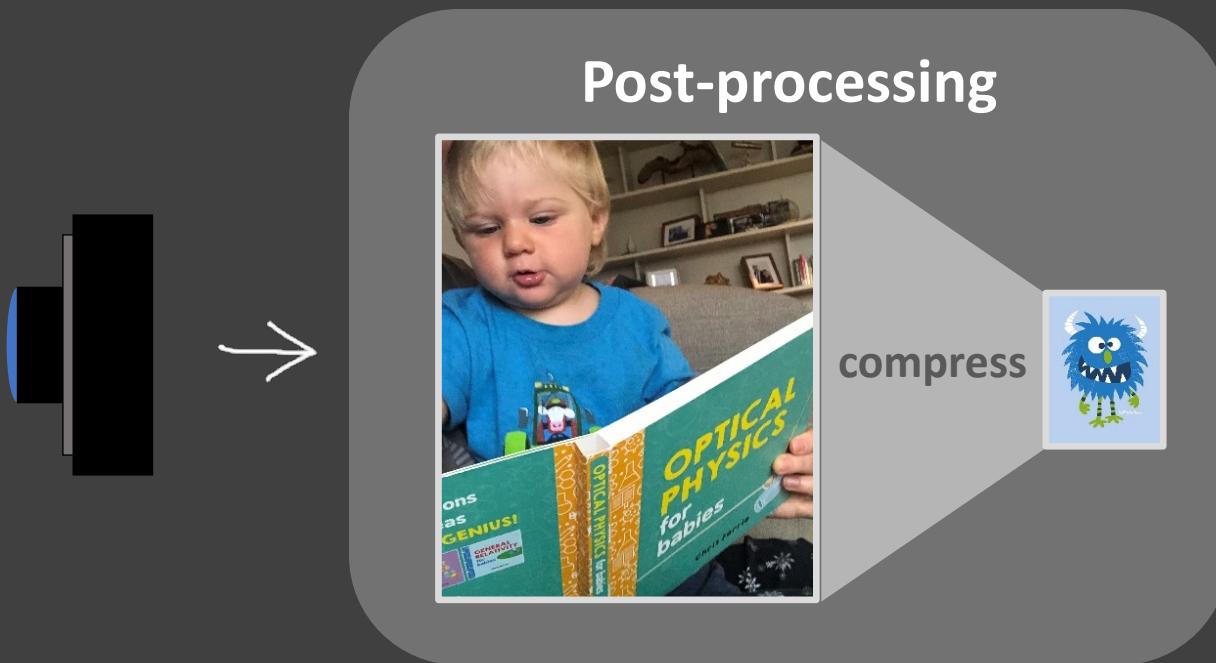

Computational Toolbox

A new way to approach imaging system design

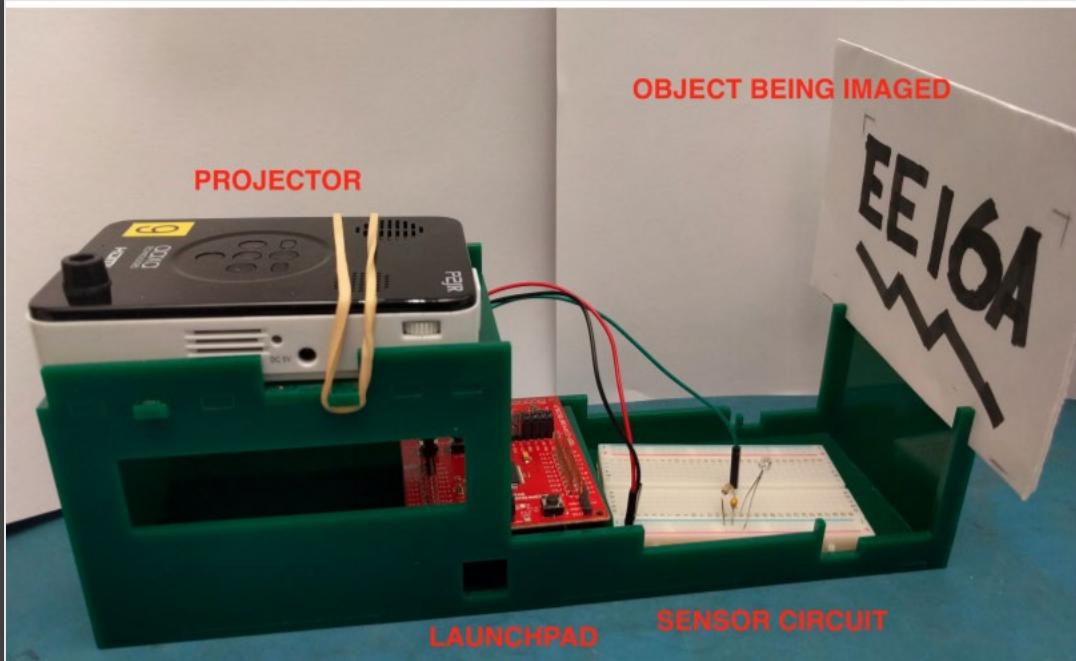

- leverage commodity hardware
- pave the way for design of new devices

Compressible images can be represented with less data

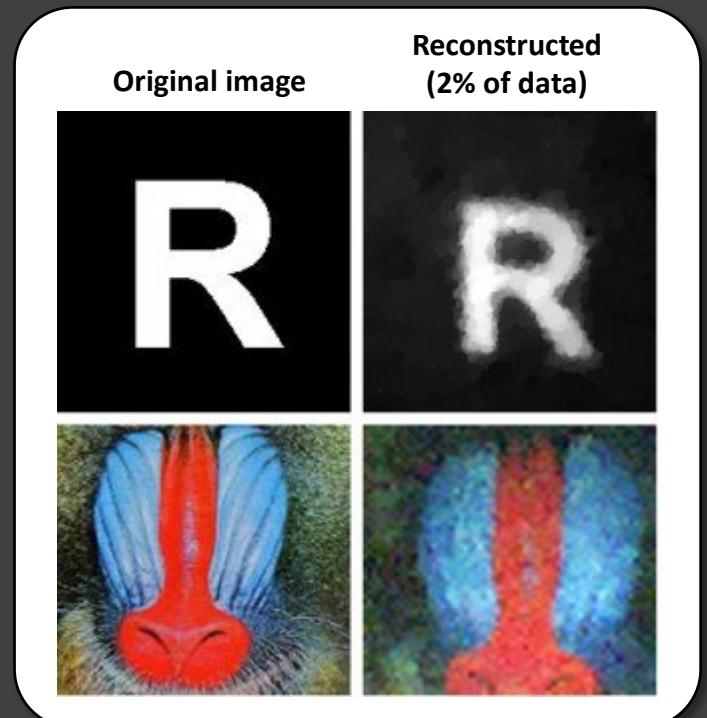

Can we compress data at the capture stage?

Yes! With compressed sensing! Example: single-pixel camera

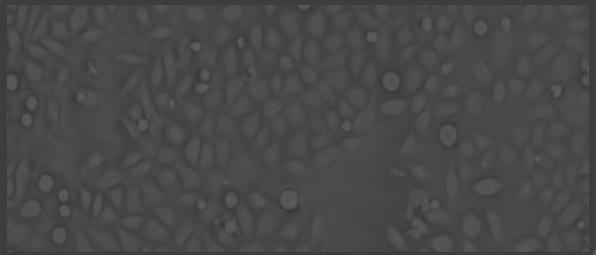

If you design the patterns on your imaging lab well, and images are compressible, you could solve with very little data!

Jonathan Ragan-Kelley

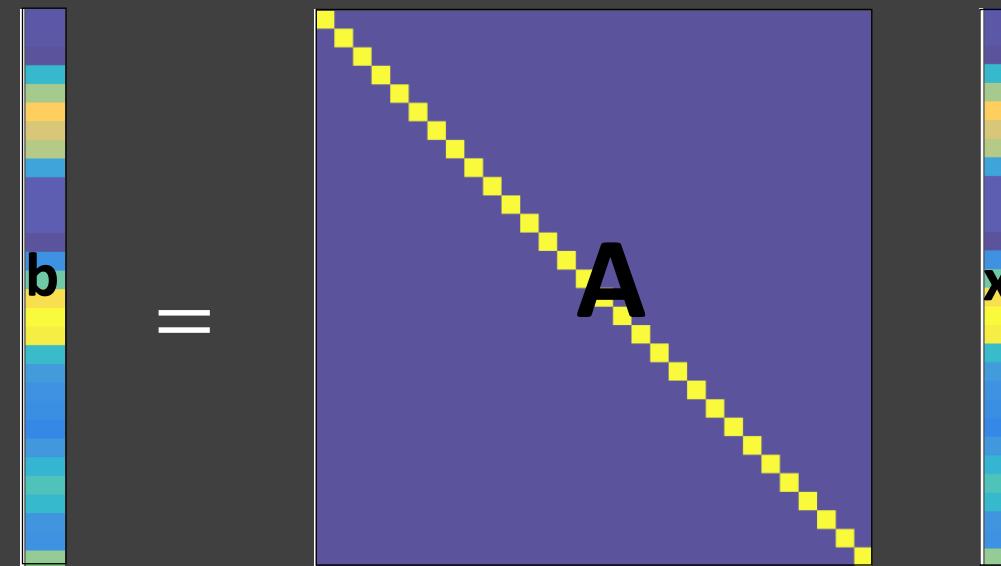

Compressed sensing is all about using prior knowledge

- Redundancy reduces sampling requirements
(The more you know, the less you need)

Traditional sensing: direct measurements

Multiplexed measurements

$$\begin{matrix} b \\ \hline \end{matrix} = \begin{matrix} A \\ \hline \end{matrix} \begin{matrix} x \\ \hline \end{matrix}$$

What makes a good sensing matrix?

A is orthogonal

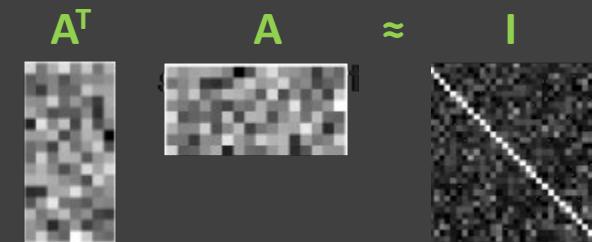

$$A^T \quad A \quad = \quad I$$

Compressed sensing solves underdetermined problems using sparsity

$$\begin{matrix} b \\ \hline \end{matrix} = \begin{matrix} A \\ \hline \end{matrix} \begin{matrix} x \\ \hline \end{matrix}$$

What makes a good sensing matrix?

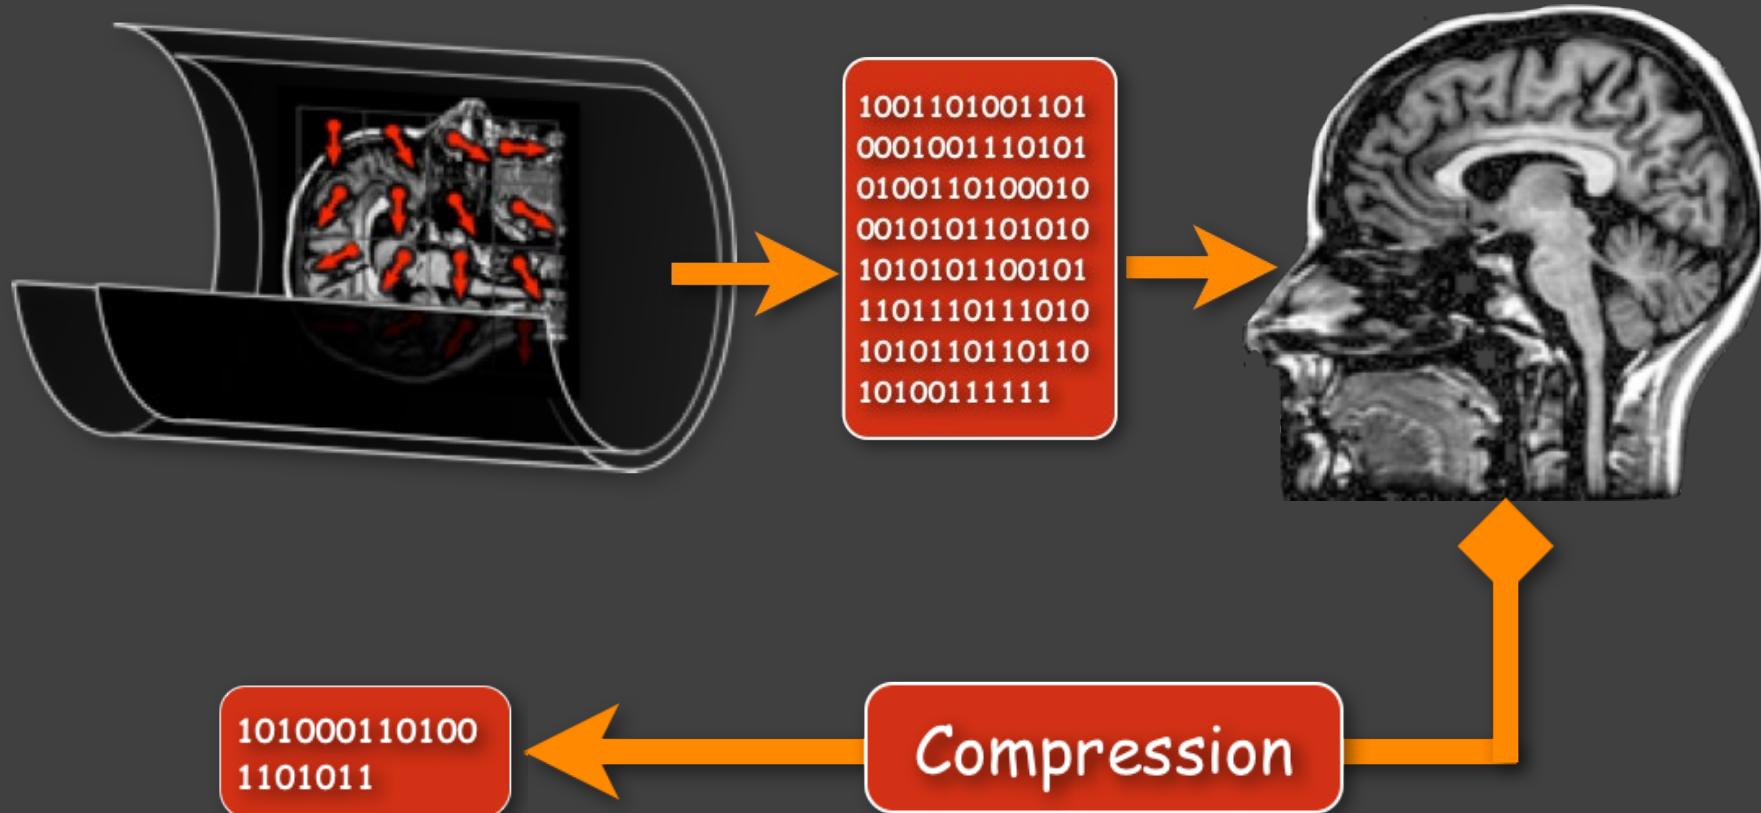

A is (almost) orthogonal

$$A^T \quad A \quad \approx \quad I$$

Compressed Sensing MRI

Medical images are compressible

Standard approach: First collect, then compress

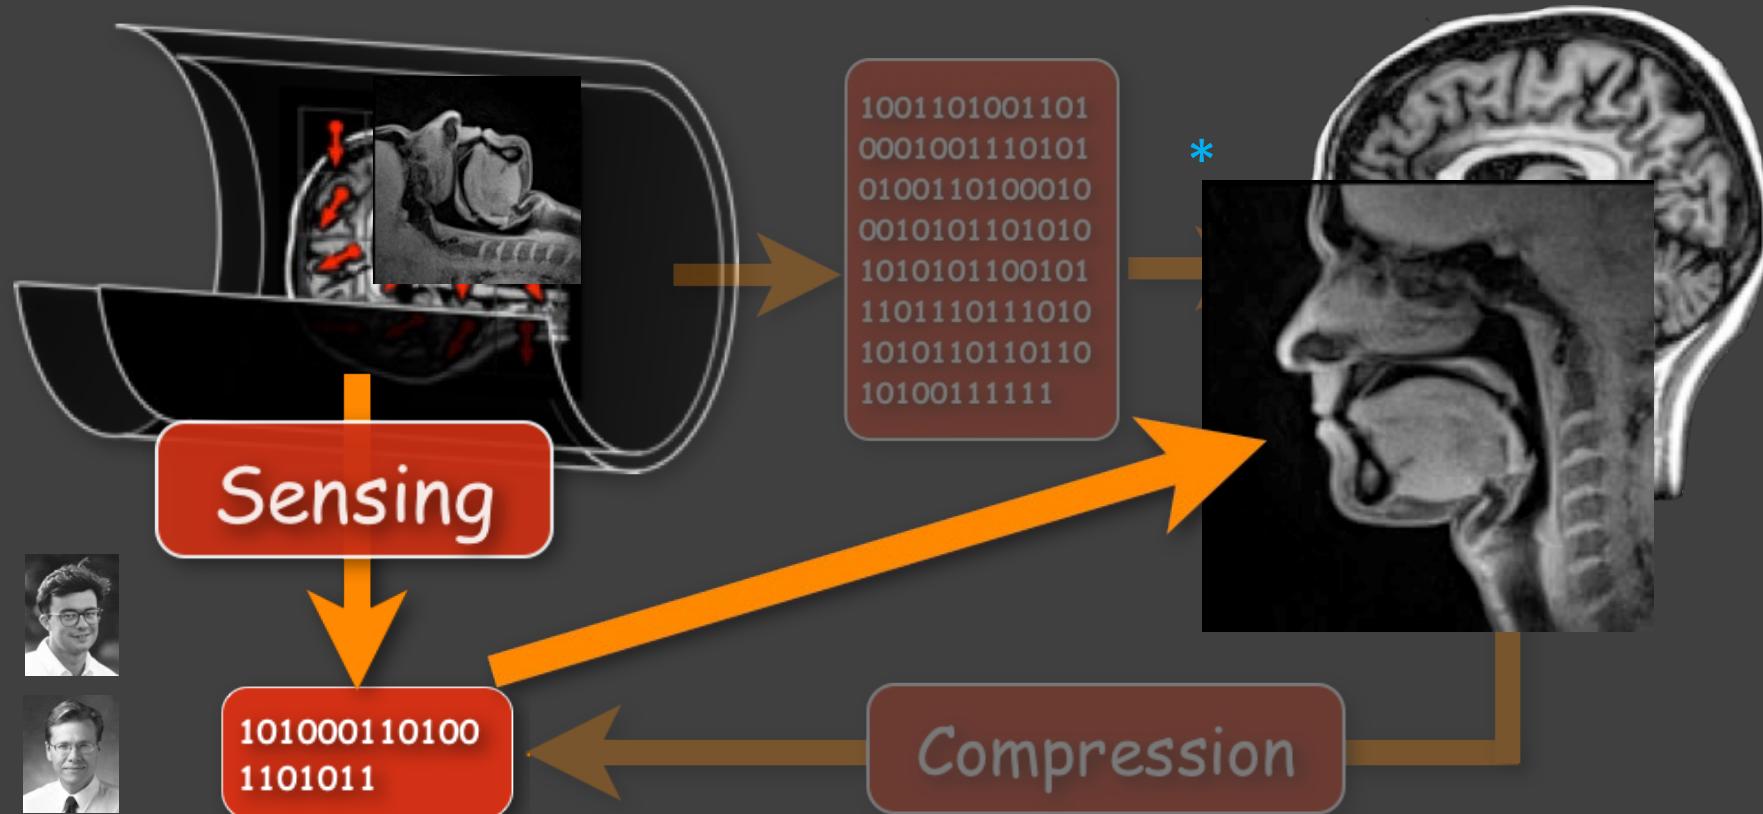

Michael Lustig's Lab

Compressed Sensing MRI

Medical images are compressible

New approach: Acquire “compressed” data directly!

Image reconstruction is nonlinear optimization

$$\arg \min_{\mathbf{x} \geq 0} \left\| \begin{array}{c} \text{b} \\ \vdots \\ \text{b} \end{array} - \begin{array}{c} \mathbf{A} \\ * \\ \mathbf{x} \end{array} \right\|_2^2 + \lambda \left\| \Phi \begin{array}{c} \text{b} \\ \vdots \\ \text{b} \end{array} \right\|_1$$

The diagram illustrates the optimization problem for image reconstruction. It shows a stack of images on the left, followed by a vector \mathbf{b} . Below \mathbf{b} is a minus sign, followed by a matrix \mathbf{A} and a vector \mathbf{x} separated by a multiplication symbol (*). To the right of the multiplication is a square root symbol with a 2 inside, indicating the squared Frobenius norm. This is followed by a plus sign and a lambda symbol (λ). To the right of the lambda symbol is a vertical bar with a 1 inside, indicating the L1 norm. Above the vertical bar is a matrix Φ . An arrow points from the text "Sparsity basis" to the matrix Φ .

Outlook: Computers and optics should talk more

Hardware Toolbox

Computational Toolbox

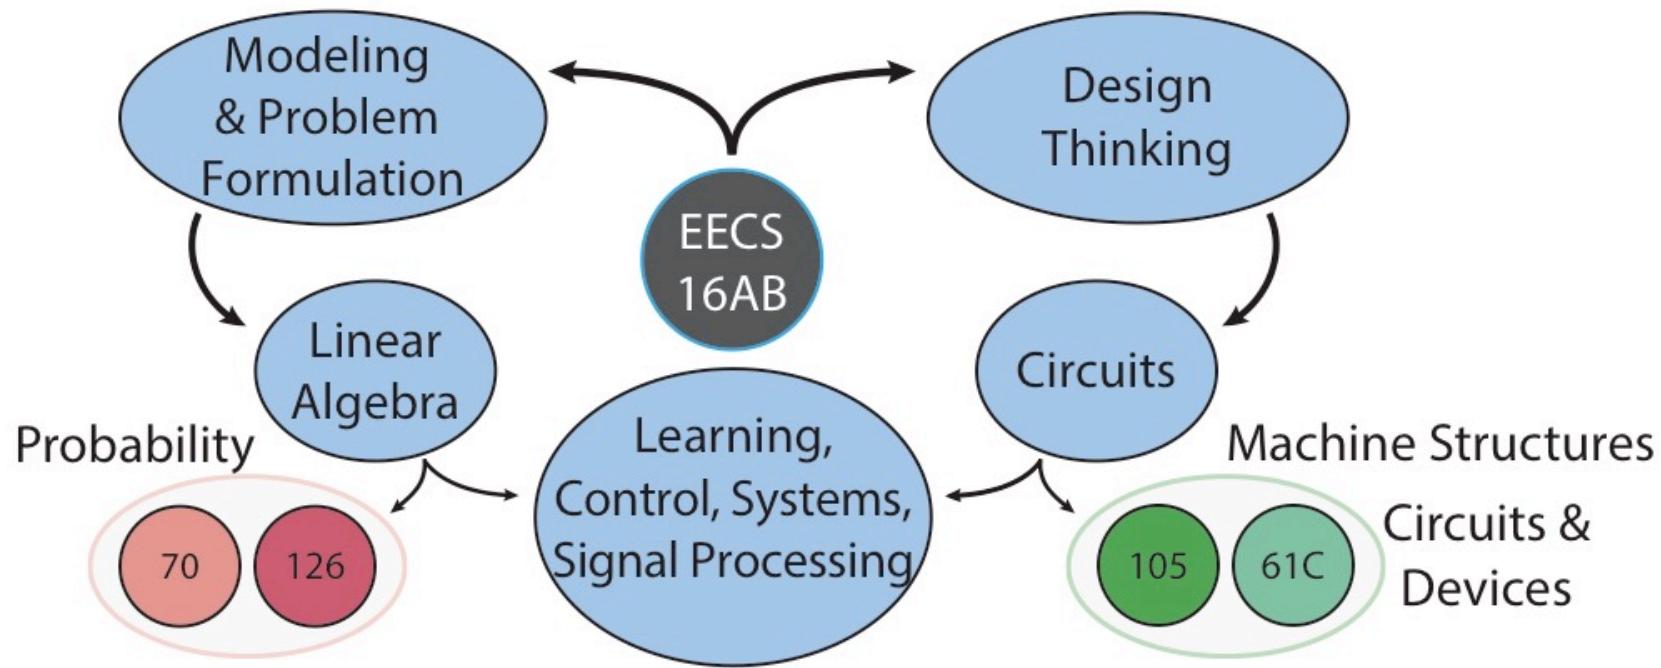

Pushing the limits of imaging can be done with existing physics and commodity hardware.

Enough about me...

- Congrats! This year has not been easy!
- What you have accomplished this semester:
 - Built a camera
 - Built two types of touchscreens
 - Built your own GPS system
- If you liked the class, please:
 - Thank your TAs!
 - apply to become one! (see piazza post, due May 2)
- This is just the beginning...

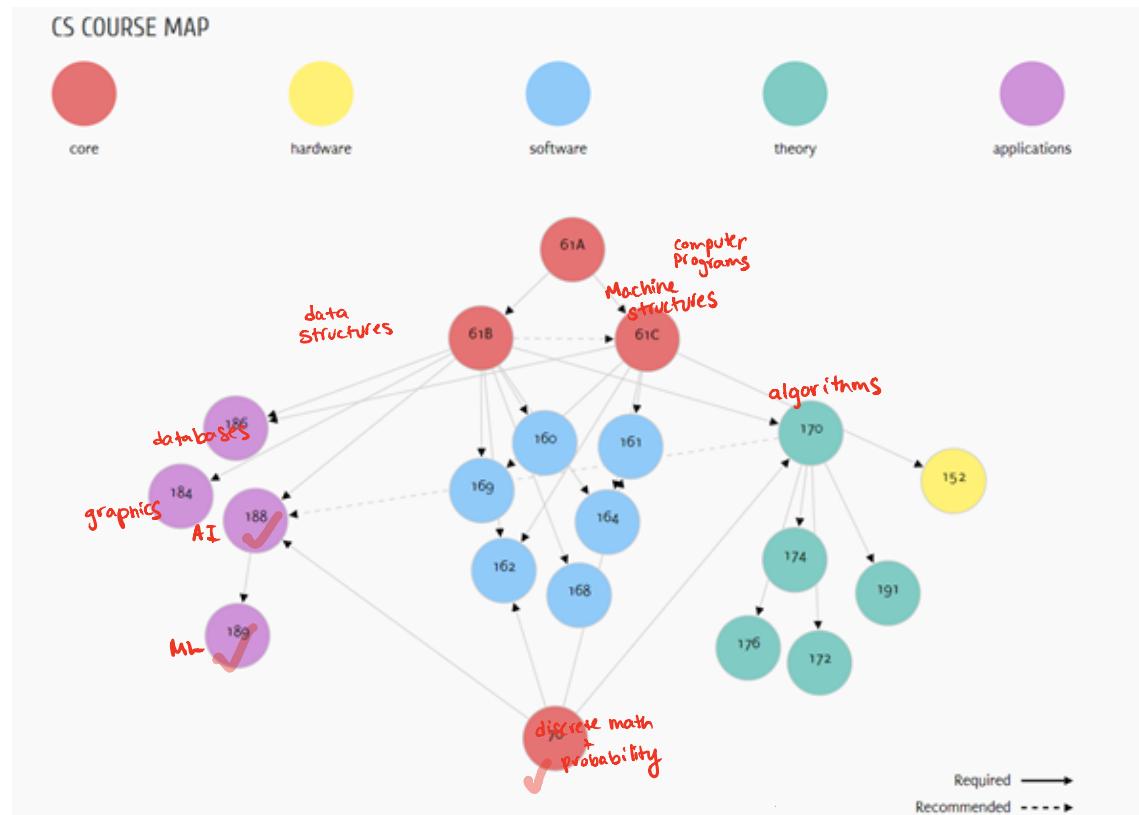

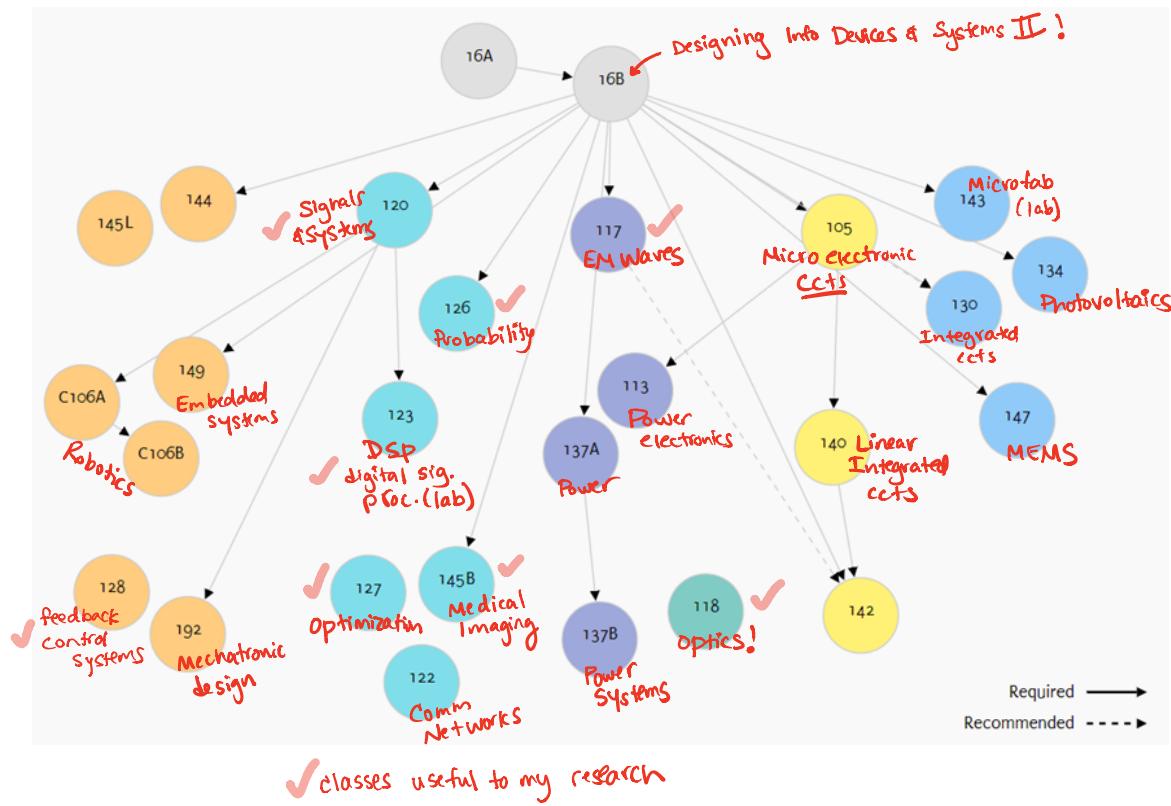

How to approach something unfamiliar
and systematically build understanding

Linear Algebra: conceptual tools to model
Circuits: How to go from model to design, grounded in physical world

Intro to foundational concepts in Machine Learning

EECS course maps:

If you liked Linear Algebra, you'll love:
(M1, M3)

- EECS 70: probability
EE120: signals & systems
↳ EE123 Digital Signal Processing (lab) ↳ e.g. gold codes, correlations
communications
EECS 126: graph transitions, wireless systems, using probability
↳ e.g. Page Rank, pumps ↳ like GPS
EE127: optimization theory → how to make things optimal! (mathematical)
CS 188: } AI/ML ← practical implementations for big data
CS 189: } uses optimization,
EECS C106AB: } controls + Robotics ← eigenvalues!
